

OpenCog consists of the following:

- A graph database that holds terms, atomic formulae, sentences and relationships as hypergraphs, giving them a probabilistic truth-value interpretation, dubbed the AtomSpace.
- A satisfiability modulo theories solver, built in as a part of a generic graph query engine, for performing graph and hypergraph pattern matching (isomorphic subgraph discovery).
- An implementation of a probabilistic reasoning engine based on probabilistic logic networks (PLN).
- A probabilistic genetic program evolver called Meta-Optimizing Semantic Evolutionary Search, or MOSES, originally developed by Moshe Looks, who is now at Google.
- An attention allocation system based on economic theory, called ECAN.
- An embodiment system for interaction and learning within virtual worlds based in part on OpenPsi and Unity.
- A natural language input system consisting of Link Grammar and RelEx, both of which employ AtomSpace-like representations for semantic and syntactic relations.
- A natural language generation system called SegSim, with implementations NLGen and NLGen2.
- An implementation of Psi-Theory for handling emotional states, drives

and urges, dubbed OpenPsi.

- Interfaces to Hanson Robotics robots, including emotion modelling via OpenPsi.
