

Red Hat acquires CoresOS to help customers build, run and manage containerised applications

In a major move, Red Hat has announced its acquisition of the containerisation company, CoreOS. This US\$ 250 million deal is expected to bring momentum to a Google-created technology, called Kubernetes, used by companies to manage software running in data centres and in the cloud.

CoreOS was built to commercialise an open source product by the same name. Container technology is a key part of Kubernetes. In a public statement, a source from Red Hat said, "By combining CoreOS's complementary capabilities with Red Hat's already broad Kubernetes and container-based portfolio, including Red Hat OpenShift, we at Red Hat aim to further accelerate adoption and development of the industry's leading hybrid cloud platform for modern application workloads."

CoreOS has 130 employees, who are joining Red Hat, and has raised US\$ 50 million, according to CrunchBase—the bulk of which is from Alphabet's venture arm GV, formerly known as Google Ventures.

"The next era of technology is being driven by container based applications that span multi- and hybrid cloud environments, including physical, virtual, private cloud and public cloud platforms. We believe this acquisition cements Red Hat as a cornerstone of hybrid cloud and modern app deployments," said Paul Cormier, president, products and technologies, Red Hat.

Deutsche Bank continues with its open source journey

Not deviating from its open source path, Deutsche Bank has made some software code publicly available. The solution, known as Waltz, will help firms better understand their IT environments, allowing them to manage their technology more effectively. The move underpins the bank's goal to become a leader in the open source community.

Waltz allows organisations to gather information about their IT environment from multiple sources across the firm, including information on applications, infrastructure, data, processes and costs. It pulls the information together intelligently and displays it in a powerful, easy to use interface. The result is an unprecedented level of transparency for decision makers over their complex IT environments. This enables smarter, faster and better decisions on technology investments and allows organisations to optimise their IT architecture to meet business growth and development goals.

Waltz is part of the bank's strategy to modernise, simplify and standardise its technology. By making

the code publicly available, programmers can suggest improvements, develop new features and find innovative new uses for the software. This is fed back into the open source community, making the application even more useful for everyone. The code can be accessed via the GitHub platform.

Russell Green, head of group architecture at Deutsche Bank, said, "This is an exciting step which showcases the high level of innovation within the firm. We look forward to working with the open source community to share ideas, drive consistency across the industry and continually improve the software."

TRI extends support to Open Source Robotics Foundation

Continuing with its commitment to open source robotics software, Toyota Research Institute (TRI) has announced its contribution to the Open Source Robotics Foundation (OSRF). This is the second consecutive year that TRI is donating US\$ 1 million to OSRF. With the help of TRI's gift, OSRF plans to improve the features and capabilities of the Robot Operating System (ROS) and Gazebo to stimulate their use in automotive applications.

OSRF offers the global robotics community access to open source robotics software and development tools. Founded by members of the community, it is an

independent non-profit organisation that supports the development, distribution and adoption of open source software for use in robotics research and education. The group oversees the development of ROS, a flexible framework for writing robot software, and Gazebo, a 3D multi-robot simulator.

Team OSRF is confident that the forthcoming second generation of ROS, called ROS 2, will be used heavily in developing software and supporting systems for autonomous vehicles. In addition to this donation, TRI is also participating in a two-year research agreement on a variety of projects with the Open Source Robotics Corporation (OSRC). This is a for-profit subsidiary of OSRF.

Software developers can use Gazebo to help with simulated testing to ensure their systems achieve a high level of safety in operation. Over the past year, two
