

Service providers will be able to use white boxes with greater efficiency

To create an ecosystem that offers application and hardware options from multiple vendors, AT&T has open-sourced its Disaggregated Network Operating System, or dNOS project, in order to simplify OS development for other network objects. The Linux Foundation will take over the project, which seeks to develop a software framework to speed the adoption and use of white boxes in service provider infrastructure.

AT&T is already a backer of the ONAP platform for SDN and NFV. Just as the ONAP platform has become the open network operating system for the network cloud, the dNOS project aims to be the open operating system for white boxes, the company said.

The project will support existing network protocols and offer expansion capabilities to support new tools, like the open source programming language P4. Human resources from AT&T Labs and AT&T Vyatta will be key contributors to the project.

AT&T is working to provide the industry with a more open, flexible and cost-effective alternative to traditional integrated networking equipment. Open sourcing the dNOS project will ensure software developers, network operators, cloud providers, hardware makers and networking application developers can quickly create new white box infrastructure to meet evolving customer requirements — and do it in a more cost-effective way. The code and collateral transition will begin soon.

major open source self-driving vehicle software systems were independently developed in the ROS community and released under an open source licence.

“Open source robotics software systems are becoming more pervasive in the automotive community. TRI is helping to enhance the quality and robustness of our systems to meet the needs of automotive users. TRI also enables us to conduct vital maintenance and updates on our public-facing services, which ensures our systems continue to be accessible and perform flawlessly,” said OSRF CEO, Brian Gerkey.

Godot Engine adds VR support

Godot Engine contributors have finally presented the much awaited Godot 3.0.

With this new release, Godot Engine, an open source game development tool, has released a new build too. In the new release, it has introduced support for VR projects into the mix.

Both open source and free to use, Godot Engine is a game development engine that offers a wide variety of developers a chance to dabble in creating VR games.

The 3.0 release of Godot Engine introduces ARVRServer implementation. Right now, this means that developers will be able to create VR projects for either SteamVR or Google Cardboard-style mobile VR. But down the line, the Godot Engine team says that AR support is expected as well.

The release comes with a brand new renderer with state-of-art PBR workflow for 3D. Other features include an improved assets pipeline, GDNative, to load native code as plugins, C# 7.0 support and Bullet as the 3D physics engine.

Godot Engine 3.0 has an almost entirely new core, as well as several top-notch new features. In Godot 3.0, writing shaders is very easy, and it uses a custom language that supports most of the GLSL specifications. You can check out the full patch notes at the Godot Engine website for more details on all the new features.

NextFlex to create flexible circuit system

Setting the stage for smart technologies catering to the Internet of Things (IoT) and sensor applications like wearable devices, a US Air Force Research Laboratory-

led project is working with NextFlex. The combined efforts have resulted in the functional samples of flexible Arduino circuit board systems made by using a flexible hybrid electronics (FHE) manufacturing process.

Lightweight, low-cost and flexible electronic systems are the key to next-generation smart technologies for military as well as other commercial applications.

And the possibilities for FHE technology are virtually limitless. “Proving the manufacturability of this technology through an open source platform will expand FHE’s reach even further by providing everyone — from industrial
