

Choosing a CMS Solution for Java Application Architecture

In this article, the author presents a comparative study of different CMS solutions, discussing their merits and demerits when used in Java application architecture.

With widespread access to the Internet, people prefer to do many of their favourite jobs online—like shopping, banking, attending meetings, etc. Earlier, tasks requiring online (Web based) technology proved to be costly due to resources and other constraints. Nowadays, with the invention and widespread usage of cloud computing as well as access to shared or rentable resources over the Net, people prefer online computing to a great extent.

A CMS (content management system) comprises a set of techniques and features to handle shared data and to manage the related workflow. Knowledge management sites (sharing articles and technical query forums) are examples of a CMS. Content management is coupled with workflow management (like a series/sequence of predefined workflows for handling content). To make it simpler, since the volume of users online is too huge for handling unauthorised content publishing, a gateway is provided for the approval process (like upload, accept, approve, publish, share) which is defined with different stages, before becoming available to public users.

Choosing a CMS solution

There are a lot of sophisticated CMS solutions available in the industry, but you must find what's most appropriate for your requirement. So let's discuss some of the most popular CMS solutions and also do a comparative study on them.

Do keep in mind that this article does not cover the usage and complete technical background of the CMS solutions discussed as that may deviate from the topic of interest. Rather, it gives an introduction to these solutions and straight away runs through their pros and cons by doing a comparative analysis.

Designing CMS based architecture

Before getting into the CMS solutions and a comparative study, let's first understand what makes a CMS website comprehensive and hence appreciated by common users. For this, we have to analyse various common requirements of a CMS solution and see how to handle them.

We need to understand what the third party tools required for the development of a CMS are and how we get support from them. It also means that we need to do a thorough analysis
