

Last but not the least, let us discuss 'match'. Rust provides pattern matching through the *match* keyword, which can be used in switch statements in C. An example of *match* is shown in the snippet below:

```
fn main() {
    let number = 13;
    // TODO ^ Try different values for 'number'

    println!("Tell me about {}", number);
    match number {
        // Match a single value
        1 => println!("One!"),
        // Match several values
        2 | 3 | 5 | 7 | 11 => println!("This is a prime"),
        // Match an inclusive range
        13..19 => println!("A teen"),
        // Handle the rest of cases
        _ => println!("Ain't special"),
    }

    let boolean = true;
    // Match is an expression too
    let binary = match boolean {
        // The arms of a match must cover all the possible
        // values
        false => 0,
```

```
        true => 1,
        // TODO ^ Try commenting out one of these arms
    };

    println!("{}", -> {}, boolean, binary);
}
```

This concludes our exploration of the basics of the Rust programming language. Rust has many more unique features to offer, like custom macros, which are beyond the scope of this article. To get more details about these, official Rust documentation can be referred to. [END](#)
