

Yahoo open sources its Big Data supported search tech

Months after being acquired by Verizon, Yahoo has decided to open source its Big Data processing and serving engine called Vespa. The technology was used exclusively for search queries on key Yahoo products, including Yahoo News and Flickr, among others.

Verizon-owned Oath, which serves as the parent company of Yahoo, claims that Vespa processes and serves content and ads almost 90,000 times every second, with latencies in the tens of milliseconds. It is even supposed to handle keyword and image searches on a huge scale, with a few hundred queries per second on tens of billions of images.

Developer teams can leverage Vespa to pick content through SQL-like queries and text search, organise matches and generate data-driven pages, as well as write data in real-time. The technology is capable of distributing data and computation over several machines at once.

“By releasing Vespa, we are making it easy for anyone to build applications that can compute responses to user requests, over large data sets, in real-time and at Internet scale — capabilities that up until now have been within the reach of only a few large companies,” Vespa’s distinguished architect Jon Bratseth wrote in a blog post. Vespa can be run on-premise or in the cloud and comes both in Docker images and rpm packages. Its code is available in a GitHub repository along with detailed documentation.

continue its initiatives, which are dedicated to promoting and protecting open source software and its communities.

Intel releases Clear Containers 3.0 with Go language construction

Intel’s Clear Linux has launched a new generation of its containers project Clear Containers. Debuted as the Clear Containers 3.0, the new version brings support for leveraging code used for namespace-based containers and improves integration in the container ecosystem.

The most significant change in Clear Containers 3.0 is its Go language build. Intel’s Clear Linux team has finally decided to switch from C language to Go. The

new Clear Containers version also comes with a new agent based on the libcontainer library. Users can use the library to apply policies and filters such as SELinux and Seccomp within the Clear Container guest mode.

In addition to the major improvements to Clear Containers, Intel has upgraded CC-runtime that now includes compatibility with the OCI runtime specification and Docker engine. Users can also run the platform using Kubernetes through CRI-O. This new development enables users to run both trusted and untrusted workloads in a Kubernetes cluster on bare metal.

Clear Containers 3.0 can be downloaded from its GitHub repository.

Huawei and SUSE to build mission-critical server for SAP applications

Huawei and SUSE have expanded their ongoing partnership, and will be developing a mission-critical server that runs SAP applications. The announcement has come months after the two companies agreed to make SUSE Enterprise Server compatible with KunLun RAS 2.0.

The new solution will be based on Huawei’s 16-/32-socket and run SUSE Linux Enterprise Server. Supporting 8, 16 and 32 bit Intel processors with up to 32TB of onboard storage, sources claim that the KunLun mission-critical server

can achieve a 30,000 per cent improvement in reliability. It will have technologies such as kPar physical partitioning, memory module hot swap and predictive failure analysis.

“This solution will ensure continuous, stable running of enterprise, business-critical applications and reduce unplanned downtime. Supporting memory online maintenance, it reduces unplanned system outages caused by memory faults to almost zero, thereby boosting the reliability of enterprise critical applications,” said Qiu Long, president of the Huawei IT server product line, in a joint statement.

SUSE has enabled its platform with enterprise-class Linux OS kernels, along
