

Creating a Web Application Using Azure App Services

'Azure App Services' enables the development of powerful apps for any platform and any device. Let's try and build a simple Web application using this PaaS offering from Microsoft Azure.

The global industry is increasingly leaning towards Platform as a Service (PaaS), which has advanced considerably over time. Today, PaaS uses several programming languages such as .NET, Java, PHP, Python and Ruby.

Microsoft Azure and its services

Microsoft Azure is one of the most dominant cloud services providers in the market. Microsoft Toolsets provides an easy way to deploy applications that are built on a platform like Java and .NET.

Microsoft Azure comes with some core concepts that are important to understand. Its services are available in 36 regions around the world, with plans announced for four additional regions. Details regarding these regions are available at <https://azure.microsoft.com/en-in/regions/>. To view products or services available, based on the region, you can go to <https://azure.microsoft.com/en-in/regions/services/>. 'Resource Groups' in Microsoft Azure is a logical container. It can be used to group different resources such as Microsoft Azure App Services, SQL databases, and storage accounts available in Microsoft Azure.

An App Service Plan (ASP) comprises the instance size and instance count on which the application is hosted, as well as its features. There are different capabilities and limits within ASPs. It is important to understand that ASPs can be shared by multiple applications and deployment slots are usually on the same ASP; however, we can change the ASP for the slots too. If

you want to understand how pricing works in Microsoft Azure, you should explore Azure Calculator at <https://azure.microsoft.com/en-in/pricing/calculator/>.

Microsoft Azure App Services

App Services is one of the most popular offerings from Microsoft Azure. Web Apps are a PaaS offering that have computing resources and runtime environments managed by Microsoft Azure.

For Azure App Services, five pricing tiers are available – free, shared, basic, standard and premium.

- **Free:** Try this to implement a proof-of-concept.
- **Shared:** This is for basic Web applications or static websites.
- **Basic:** This is for development/test environments.
- **Standard:** This is for Web and mobile applications in the production environment.
- **Premium:** This is for enterprise scale and integration.

App Services can be easily used in DevOps practices too. Visual Studio Team Services can be used for continuous integration and delivery, or continuous deployment using different tasks and ways in different environments, with approved scenarios.

To check how these services work, go to <https://azure.microsoft.com/en-us/try/app-service/>. Select **Web App**. Click on *Continue* and follow the rest of the steps indicated.
