

Unmounting the directory

The unmount process is exactly like unmounting regular directories. To unmount a directory, execute the following command:

```
$ umount /mnt
```

...or:

```
$ fusermount -u mountpoint
```

Persistence directory mounting

If a directory is mounted manually, then the mount point will not be persistent across machine reboots. To create this persistence, we can configure auto-mount during boot time. To do this, a passwordless SSH has to be configured between two machines, as explained earlier.

The following entry must be added to the `/etc/fstab` file:

```
sshfs#jarvis@192.168.10.20:/home/jarvis/src /mnt fuse defaults 0 0
```

In the above command:

- `sshfs#` indicates that the mount must be performed using SSHFS
- `jarvis` is a user

- `192.168.10.20` is an IP of a remote host
- `/home/jarvis/src` is a directory from the remote host
- `/mnt` is a mount point
- `fuse` is a file system type
- `defaults` gives the options of the file system
- The last two parameters are related to backup and error checking

Miscellaneous options

This section discusses various SSHFS options that can be used to tune its default behaviour.

- `-C`: Enables compression
- `-d`: Enables debugging mode
- `-f`: Enables foreground mode
- `-o cache=no`: Disables caching mechanism
- `-o cache_timeout=N`: Sets cache timeout value in seconds

SSHFS is a very useful utility and it really makes life easier. Another advantage is that the behaviour of the remote mount point is identical to that of the local mount point.

Users can create, delete, modify and perform other file system supported operations on this mount point. **END** 🐧
